

Installation Guide

- 1) Install the AppExchange Package
- 2) Create an Alert at: <https://www.google.com.au/alerts> or <https://www.google.co.uk/alerts> or the applicable google site for your country, once created change the type of alert to an RSS Feed.

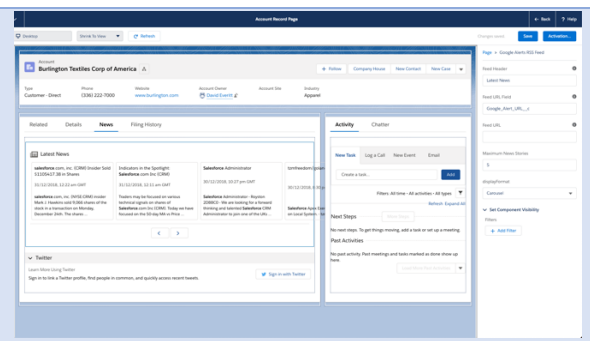

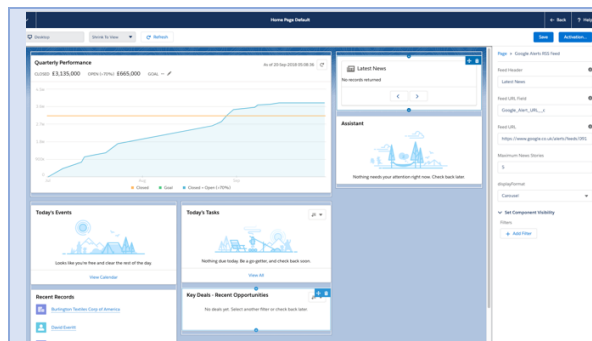

- 3) Click on the RSS icon to get taken to the feed URL, the contents are in XML. The URL should look something like <https://www.google.co.uk/alerts/feeds/09129951527648623769/180368199555198656751>. This is your Google Alert URL to be used later.
- 4) In Salesforce create a Remote Site Setting record for the base of the URL. So, in the example above you would create one for <https://www.google.co.uk>.

- 5) Now in Salesforce the configuration differs depending on whether you are adding the component to a page with a static URL (such as the homepage) or if you want the URL to be stored in a field on the object and have it change based on the record you are looking at.

Homepage (or other page where the URL is constant)	Account Record Detail Page (or other page where the URL is dynamic)
In the case of a static URL, simply drag the component 'Google Alert RSS Feed' into the Lightning App Builder page and specify the URL from step 3 in the 'Feed URL' attribute.	The Package has added a field called Google_Alert_URL__c to the Account object, just add this to the Page Layout to allow users to update this value.

Then drag the component to the Record Detail Page in the Lightning App Builder and specify the field required in the 'Feed URL Field' attribute.

This can also be done on other objects, but you'll have to create the field yourself. A formula field on Opportunity that references the Account field might be useful.
